

Stationary Rational Bubbles in Non-Linear Business Cycle Models of Closed and Open Economies

Robert Kollmann
Université Libre de Bruxelles & CEPR

November 5, 2019

Contributions:

(1) new type of sunspot equilibrium that is shown to exist in standard DSGE models, even when Blanchard & Kahn conditions hold. Key mechanism: non-linearity.

(2) new sunspot generates BOOM-BUST cycles

**(3) In multi-country model with complete financial markets: BUBBLES must be PERFECTLY correlated across countries
⇒ Bubbles generate SYNCHRONIZED business cycles**

**Analytical contribution:
non-linear DSGE models have more
stationary equilibria than you think!**

This paper shows: standard **NON-LINEAR
DSGE models have MULTIPLE stationary
equilibria, even when the linearized versions
of these models have unique solution**

**⇒ In non-linear model: stationary
fluctuations **WITHOUT** shocks to TFP,
preferences, policy**

⇒ Blanchard & Kahn (1980): conditions for existence of unique **stable** solution of **linear(ized)** models are **IRRELEVANT** for non-linear models

⇒ Sunspot equilibria in non-linear models studied here look like ‘BUBBLES’:

- economy may temporarily diverge from steady state;**
- with exogenous probability economy later reverts to steady state**

BOOM-BUST CYCLE:

- consistent with rational expectations**
- ‘rational bubbles’ are stationary**

Similarities and important differences with rational bubbles in linear models (Blanchard, 1979)

- Like Blanchard (1979) I focus on models whose linearized versions have unique non-explosive equilibrium
- Key difference: bubbles in non-linear models are STATIONARY
- Blanchard bubbles (linear models): *expected* trajectories explode to $\pm \infty$

Consider non-linear model with just 1 non-predetermined variable (no exogenous driver)

$$E_t G(Y_{t+1}, Y_t) = 0$$

Linearization (around steady state):

$$E_t y_{t+1} = \lambda \cdot y_t, \quad y_t \equiv Y_t - Y^{SS}$$

Linearized model has unique non-explosive solution iff $|\lambda| < 1$. Unique solution is: $y_t = 0$
(Blanchard & Kahn (1980), Prop. 1)

$E_t y_{t+1} = \lambda \cdot y_t$, $\lambda > 1$; y_t : scalar jump variable

Unique stable solution: $y_t = 0$

Blanchard (1979)

Bubble: $y_{t+1} = (\lambda / (1 - \pi)) \cdot y_t$ with probability $1 - \pi$

$y_{t+1} = 0$ with probability π

$\lim_{s \rightarrow \infty} E_t y_{t+s} = \pm \infty$ if $y_t \neq 0$

expected path of bubble diverges to $\pm \infty$

**Expected path of bubbles in non-linear
DSGE described here do NOT diverge to $\pm \infty$**

● **Explosive (expected) trajectories are problematic:**

▶ **accuracy of linear model approximations breaks down far from point of approximation; non-negativity & technological feasibility constraints may be violated**

Example: with decreasing returns to capital, explosive trajectory of capital & output is INFEASIBLE

⇒ **LINEAR APPROXIMATION UNSUITABLE FOR ANALYZING RATIONAL BUBBLES**

- **By contrast: non-linear analysis here takes non-negativity constraints, decreasing returns & risk aversion into account**
- **Decreasing returns & risk aversion generate stabilizing forces that prevent explosive trajectories**
- **Stationary rational bubbles in non-linear models are generally one-sided (capital over-accumulation, but no under-accumulation)**
[By contrast: Blanchard bubbles in linear models can be positive or negative]

● Rational bubbles in non-linear model can induce fluctuations that are close to deterministic steady state most of the time

⇒ unconditional mean of endogenous variables close to deterministic steady state

● Non-linear DSGE models driven just by stationary bubbles can generate persistent fluctuations of real activity & capture key business cycle stylized facts

Note: Can construct linearized DSGE models with non-explosive sunspot equilibria:

$E_t y_{t+1} = \lambda \cdot y_t$ **need** $|\lambda| \leq 1$. $\Rightarrow y_{t+1} = \lambda \cdot y_t + \varepsilon_{t+1}$ is stationary solution for any $\{\varepsilon_{t+1}\}$ with $E_t \varepsilon_{t+1} = 0$

Needed ingredients:

- Increasing returns, externalities (e.g., Schmitt-Grohé (1997), Benhabib and Farmer (1999))
- Financial frictions (e.g., Martin and Ventura (2018))
- Overlapping generations (e.g., Woodford (1986), Galí (2018))

Specific assumptions & calibrations that deliver $|\lambda| < 1$ can be debatable & fragile (e.g. in standard OLG model: need $r \leq g$)

By contrast, paper here argues that very standard DSGE models with $|\lambda| > 1$ can deliver stationary sunspot equilibria, if non-linearities are considered.

Related contributions

- **Bacchetta, van Wincoop & Tille “Self-fulfilling Risk Panics” (AER 2012): stylized asset pricing model whose linearized version has unique solution, but non-linear model has multiple equilibria iff sunspot shocks are HETEROSKEDASTIC.**

My paper highlights importance of heteroskedasticity for multiplicity of equilibria in non-linear DSGE business cycle model.

● Holden (2016ab) shows that multiple equilibria emerge when occasionally binding constraints (e.g. ZLB) are integrated into otherwise standard linear model.

■ **By contrast: my analysis considers FULLY non-linear models.**

■ **All model equations are non-linear**

■ **All relevant non-negativity constraints are imposed.**

■ **Model solutions here are globally accurate.**

■ **Multiple equilibria here have “bubbly” dynamics (different from Holden, 2016ab)**

Basic intuition I:

Consider non-linear model with just 1 non-predetermined variable (no exogenous driver)

$$E_t G(Y_{t+1}, Y_t) = 0$$

Linearization (around steady state):

$$E_t y_{t+1} = \lambda \cdot y_t, \quad y_t \equiv Y_t - Y^{SS}$$

Linearized model has unique non-explosive solution iff $|\lambda| < 1$. Unique solution is: $y_t = 0$
(Blanchard & Kahn (1980), Prop. 1)

● RESULT

When $|\lambda| > 1$, the non-linear model can have stationary sunspot equilibrium

● IDEA

$$E_t G(Y_{t+1}, Y_t) = 0 \iff G(Y_{t+1}, Y_t) = \varepsilon_{t+1} \text{ with } E_t \varepsilon_{t+1} = 0$$

$$\Rightarrow Y_{t+1} = \Lambda(Y_t, \varepsilon_{t+1}) \cdot \quad \varepsilon_{t+1}: \text{“sunspot shock”}$$

Even if $|\Lambda_Y| > 1$, there may exist process $\{\varepsilon_{t+1}\}$ with $E_t \varepsilon_{t+1} = 0$ such that $\{Y_{t+1}\}$ is stationary.

Note: when white noise $\{\varepsilon_{t+1}\}$ is fed into $Y_{t+1} = \Lambda(Y_t, \varepsilon_{t+1})$, then $\{Y_{t+1}\}$ diverges if $|\Lambda_Y| > 1$.

Key requirements for stationary solution:

- $Y_{t+1} = \Lambda(Y_t, \varepsilon_{t+1})$ has to be **NON-LINEAR** in ε_{t+1}
- **Distribution of ε_{t+1} has to depend on Y_t**

$$Y_{t+1} \cong \Lambda(Y_t, 0) + \Lambda_{\varepsilon}(Y_t, 0) \cdot \varepsilon_{t+1} + \frac{1}{2} \Lambda_{\varepsilon\varepsilon}(Y_t, 0) \cdot (\varepsilon_{t+1})^2$$

$$E_t Y_{t+1} \cong \Lambda(Y_t, 0) + \frac{1}{2} \Lambda_{\varepsilon\varepsilon}(Y_t, 0) \cdot E_t (\varepsilon_{t+1})^2$$

Let $E_t (\varepsilon_{t+1})^2 = f(Y_t) \geq 0$. If $\Lambda_{\varepsilon\varepsilon}(Y_t, 0) \neq 0$ then can set

$E_t (\varepsilon_{t+1})^2 = f(Y_t)$ such that $|dE_t Y_{t+1} / dY_t| < 1$:

“MEAN REVERSION”

Example: $\Lambda_Y(Y_t, 0) > 1$, $\Lambda_{\varepsilon\varepsilon}(Y_t, 0) < 0$. Then need

$f'(Y_t) > 0$ for mean reversion: $E_t (\varepsilon_{t+1})^2$ must be

increasing in Y_t .

Basic intuition II: RBC model

$$C_t + K_{t+1} = Y_t; \quad Y_t = F(K_t), \quad F' > 0, \quad F'' < 0$$

$$\beta \{ [E_t u'(C_{t+1})] / u'(C_t) \} \cdot F'(K_{t+1}) = 1; \quad \text{assume } u''' > 0 \text{ (CRRA)}$$

Sunspot: assume $K_{t+1} \uparrow \Rightarrow C_t \downarrow \Rightarrow u'(C_t) \uparrow$,

$F'(K_{t+1}) \downarrow$ Euler eqn requires:

$$E_t u'(C_{t+1}) = E_t u'(F(K_{t+1}) - K_{t+2}) \uparrow$$

• In deterministic economy: need $C_{t+1} \downarrow$ & $K_{t+2} \uparrow$

K_{t+2} has to rise more than K_{t+1} ! \Rightarrow **K diverges**

• With stochastic sunspot: K_{t+2} random.

$u'(C_{t+1})$ is convex in $K_{t+2} \Rightarrow$ if $Var_t(K_{t+2})$ rises,

$E_t u'(C_{t+1}) \uparrow \Rightarrow E_t K_{t+2}$ can rise less than K_{t+1} !

\Rightarrow **possibility of mean reversion**

TRANSVERSALITY CONDITION (TVC)

Standard DSGE usually assume an infinitely-lived representative agent.

Optimality conditions include transversality condition:

$$\lim_{\tau \rightarrow \infty} \beta^\tau E_t u'(C_{t+\tau}) K_{t+\tau+1} = 0$$

TVC + Euler eqn. + static efficiency condit.
⇒ unique equilibrium.

When TVC does not hold: economy is “dynamically inefficient”

THIS PAPER DISREGARDS TVC

- Goal is to establish existence of stationary rational bubbles in non-linear DSGE models
- Explosive bubbles in linear (Blanchard) too violate TVC

JUSTIFICATIONS OF MODELS WITHOUT TVC

Assume that there is no TVC because agents are finitely lived (N periods)

Novel result about OLG economy:

Assume: (I) Complete financial market allow efficient risk sharing across all generations alive at dates t and $t+1$

(II) Each generation receives wealth endowment such that consumption by newborns is time-invariant share of aggregate consumption. (Under log-utility: wealth endowment of newborns has to be time-invariant share of total wealth)

THEN

an 'aggregate' Euler equation holds that is identical to the Euler equation of a representative infinitely lived household:

$$\beta E_t \{u'(C_{t+1}) / u'(C_t)\} MPK_{t+1} = 1$$

BUT: there is no TVC in the OLG economy!

**OLG structure with efficient
intergenerational risk sharing:**

**justification for macro models that lacks a
TVC, but whose other equilibrium conditions
are identical to those of standard business
cycle models (that assume infinitely lived
agents)**

Other justifications for disregarding TVC

1) Lansing (2010) disregards the TVC in a Lucas-style asset pricing models with bubbles, arguing that “agents are forward-looking but not to the extreme degree implied by the transversality condition”

2) In richer models with heterogeneous agents and distortions: equilibrium is not solution of decision problem of representative agent.

Detection of TVC violations in stochastic economies: virtually impossible, even with very long simulation runs (billions of periods):

States with very low consumption might only occur with extremely small probabilities.

Detailed Example I:

Long-Plosser RBC model with sunspots

$$u(C) = \ln(C); \quad C_t + K_{t+1} = Y_t; \quad Y_t = F(K_t) \equiv (K_t)^\alpha, \quad 0 < \alpha < 1$$

$$\text{Euler equation: } \beta E_t \{ u'(C_{t+1}) / u'(C_t) \} \cdot F'(K_{t+1}) = 1$$

$$\Rightarrow \beta E_t \{ C_t / C_{t+1} \} \cdot \alpha Y_{t+1} / K_{t+1} = 1$$

$$\Rightarrow \beta E_t \{ (Y_t - K_{t+1}) / (Y_{t+1} - K_{t+2}) \} \cdot \alpha Y_{t+1} / K_{t+1} = 1$$

$$\Rightarrow \alpha \beta \cdot E_t \{ (1 - K_{t+1} / Y_t) / (1 - K_{t+2} / Y_{t+1}) \} \cdot Y_t / K_{t+1} = 1$$

$$\Rightarrow \alpha \beta \cdot E_t \{ (1 - Z_t) / (1 - Z_{t+1}) \} / Z_t = 1,$$

$$Z_t \equiv K_{t+1} / Y_t : \text{ investment/output ratio}$$

$$\text{Textbook solution: } Z_t = \alpha \beta$$

$$\alpha\beta \cdot E_t \left\{ \frac{(1-Z_t)}{(1-Z_{t+1})} \right\} / Z_t = 1$$

Linearization around $Z = \alpha\beta$:

$$E_t z_{t+1} = \lambda \cdot z_t, \quad z_t \equiv Z_t - Z; \quad \lambda \equiv 1/(\alpha\beta) > 1.$$

$\Rightarrow z_t = 0$ is unique non-explosive solution of linearized model.

But: non-linear model has other stationary solutions.

$$\alpha\beta \cdot \left\{ \frac{(1-Z_t)}{(1-Z_{t+1})} \right\} / Z_t = 1 + \varepsilon_{t+1}, \quad E_t \varepsilon_{t+1} = 0$$

$$\Rightarrow Z_{t+1} = \Lambda(Z_t, \varepsilon_{t+1}) \equiv 1 - \alpha\beta(1/Z_t - 1) / (1 + \varepsilon_{t+1}).$$

Z_{t+1} increasing & strictly concave in ε_{t+1}

Fig.1. Long & Plosser model: investment/output ratio at $t+1$, Z_{t+1} , as function of Z_t for $\epsilon_{t+1} \in \{-0.5; 0; 0.5\}$

$$Z_{t+1} = \Lambda(Z_t, \epsilon_{t+1}) \equiv 1 - \alpha\beta(1/Z_t - 1)/(1 + \epsilon_{t+1}); \quad \alpha = 0.35, \beta = 0.99.$$

$$Z_{t+1} = \Lambda(Z_t, \varepsilon_{t+1}) \equiv 1 - \alpha\beta(1/Z_t - 1)/(1 + \varepsilon_{t+1})$$

- When $Z_t < \alpha\beta$, the model can hit zero-capital corner solution in later periods \Rightarrow restrict attention to solutions with $Z_\tau \in [\alpha\beta, 1) \quad \forall \tau$
- Support of ε_{t+1} has to be bounded below: $\varepsilon_{t+1} \geq -1 + [\alpha\beta/(1-\alpha\beta)] \cdot [1/Z_t - 1]$
 \Rightarrow distribution of ε_{t+1} must depend on Z_t !
- Let ε_{t+1} only takes two values: $-\bar{\varepsilon}_t$ and $\bar{\varepsilon}_t \cdot \pi_t / (1 - \pi_t)$ with probabilities π_t and $1 - \pi_t$, respectively, $\bar{\varepsilon}_t \in [0, 1) \Rightarrow Z_{t+1}$ takes two values:
 $Z_{t+1}^L \equiv \Lambda(Z_t, -\bar{\varepsilon}_t)$ & $Z_{t+1}^H \equiv \Lambda(Z_t, \bar{\varepsilon}_t \pi_t / (1 - \pi_t))$ with $Z_{t+1}^L \leq Z_{t+1}^H \leq 1$.
- Postulate $Z_{t+1}^L = f(Z_t)$, with $\alpha\beta \leq f(Z_t) \leq \Lambda(Z_t, 0)$ for $Z_t \in [\alpha\beta, 1)$.
Solve $Z_{t+1}^L \equiv \Lambda(Z_t, -\bar{\varepsilon}_t)$ for $\bar{\varepsilon}_t$ & substitute into $Z_{t+1}^H \equiv \Lambda(Z_t, \bar{\varepsilon}_t \pi_t / (1 - \pi_t))$

Degrees of freedom in modeling sunspot:

- bust investment/GDP ratio, Z_{t+1}^L
- conditional probability of bust, π_t

Specification I: $Z_{t+1}^L = \alpha\beta + \Delta$, $\Delta = 0.01$, $\pi = 0.5$

(When $\Delta = 0$, then $Z = \alpha\beta = 0.346$ is absorbing state; thus set $\Delta > 0$)

$$Z_{t+1}^L = \alpha\beta + \Delta, \quad \Delta = 0.01, \quad \pi = 0.5$$

Simulated series with const. probability: $\pi=0.5$

Simulated output (Y), consumption (C) and investment (I) normalized by steady state output

Lower volatility if probability of investment bust rises once investment/output ratio Z_t crosses threshold.

Simulated series with state-contingent probability of bust:

$\pi_t = 0.5$ for $\alpha\beta + \Delta = 0.356 \leq Z_t \leq 0.36$ & $\pi_t = 1 - 10^{-100}$ for $Z_t > 0.36$

Note: all business statistics pertain to HP-filtered logged variables.

Example II: RBC model with incomplete capital depreciation & endogenous labor

$U(C_t, L_t) = \ln(C_t) + \Psi \cdot \ln(1 - L_t)$, $\Psi > 0$, L_t : hours worked

$$C_t + K_{t+1} = Y_t + (1 - \delta)K_t, \quad Y_t = \theta(K_t)^\alpha (L_t)^{1-\alpha}$$

- FOCs: $C_t \Psi / (1 - L_t) = (1 - \alpha) \theta(K_t)^\alpha (L_t)^{-\alpha}$

$$E_t \beta \{ C_t / C_{t+1} \} (\alpha \theta(K_{t+1})^{\alpha-1} (L_{t+1})^{1-\alpha} + 1 - \delta) = 1$$

- Using static efficiency conditions can express C & L as functions of capital:

$$C_t = \gamma(K_{t+1}, K_t), \quad L_t = \eta(K_{t+1}, K_t)$$

Can write Euler equation as:

$$E_t [\beta \{ \gamma(K_{t+1}, K_t) / \gamma(K_{t+2}, K_{t+1}) \} (\alpha \theta(K_{t+1})^{\alpha-1} (\eta(K_{t+2}, K_{t+1}))^{1-\alpha} + 1 - \delta)] = 1$$

Euler equation:

$$E_t H(K_{t+2}, K_{t+1}, K_t) = 1$$

No bubble solution (TVC): described by policy function $K_{t+1} = \lambda(K_t)$

so that $E_t H(\lambda(\lambda(K_t)), \lambda(K_t), K_t) = 1$

Consider **bubble equilibria** such that, for any t , K_{t+1} takes one of two values $K_{t+1} \in \{K_{t+1}^L, K_{t+1}^H\}$ with exogenous probabilities π and $1-\pi$, where $K_{t+1}^L = \lambda(K_t)e^\Delta$;
 $\Delta > 0$: small positive constant

‘L’ is ‘bust’ state, in which capital stock set at t reverts to value close to ‘no-bubble’ decision rule

Euler equation

$$E_t H(K_{t+2}, K_{t+1}, K_t) = 1$$

becomes:

$$\pi H(\lambda(K_{t+1})e^\Delta, K_{t+1}, K_t) + (1-\pi) \cdot H(K_{t+2}^H, K_{t+1}, K_t) = 1$$

Economy evolves as follows:

At date t : random draw (with probab. $\pi, 1-\pi$) determines $K_{t+1} \in \{K_{t+1}^L, K_{t+1}^H\}$ where $K_{t+1}^L = \lambda(K_t)e^\Delta$

Euler equation between t and $t+1$ determines

K_{t+2}^H :

$$\pi H(\lambda(K_{t+1})e^\Delta, K_{t+1}, K_t) + (1-\pi) \cdot H(K_{t+2}^H, K_{t+1}, K_t) = 1$$

Etc. in all subsequent periods.

See paper for: • Existence proof of sunspot equilibrium: need $\Delta > 0$. Then $K_{t+1}^L < K_{t+1}^H$

Non-linear RBC model (incompl. capital depreciation) driven by bubbles

Simulated GDP, C and I series normalized by steady state GDP. Hours worked (L) normalized by steady state hours.

Example II: Dellas (1986) 2-country RBC

= 2-country version of Long & Plosser

- Countries: $i=H,F$ ('Home' & 'Foreign')
- Each country specialized in production of distinct tradable intermediate good

$$Y_{i,t} = \theta_{i,t} (K_{i,t})^\alpha, \quad K_{i,t+1} = I_{i,t} \text{ (full capital depreciation)}$$

- Each country uses local & imported intermediates to produce a non-tradable final good used for consumption & investment:

$$Z_{i,t} = (y_{i,t}^i / \xi)^\xi \cdot (y_{i,t}^j / (1-\xi))^{1-\xi}, \quad i \neq j. \quad Z_{i,t}: \text{final good,}$$

$$Z_{i,t} = C_{i,t} + K_{i,t+1}$$

$y_{i,t}^j$ amount of input j used by country i

$\frac{1}{2} < \xi < 1$: local spending bias

• Final good price: $Z_{i,t} = (p_{i,t})^\xi \cdot (p_{j,t})^{1-\xi}$

• Demand for local & imported intermediates:

$$p_{i,t} y_{i,t}^i = \xi \cdot P_{i,t} \cdot (C_{i,t} + K_{i,t+1}), \quad p_{j,t} y_{i,t}^j = (1-\xi) \cdot P_{i,t} \cdot (C_{i,t} + K_{i,t+1}), \quad i \neq j.$$

• Log utility: $U_{i,t} = \ln(C_{i,t})$

• Complete international financial markets: full risk sharing: $P_{H,t} C_{H,t} = P_{F,t} C_{F,t}$

• Market clearing for intermediates:

$$Y_{H,t} = y_{H,t}^H + y_{F,t}^H, \quad Y_{F,t} = y_{H,t}^F + y_{F,t}^F \quad \Rightarrow$$

$$p_{H,t} Y_{H,t} = \xi \cdot (P_{H,t} C_{H,t} + P_{H,t} K_{H,t+1}) + (1-\xi) \cdot (P_{F,t} C_{F,t} + P_{F,t} K_{F,t+1}),$$

$$p_{F,t} Y_{F,t} = (1-\xi) \cdot (P_{H,t} C_{H,t} + P_{H,t} K_{H,t+1}) + \xi \cdot (P_{F,t} C_{F,t} + P_{F,t} K_{F,t+1})$$

- Market clearing:

$$P_{H,t} Y_{H,t} = P_{H,t} C_{H,t} + \xi \cdot P_{H,t} K_{H,t+1} + (1-\xi) \cdot P_{F,t} K_{F,t+1}$$

$$P_{F,t} Y_{F,t} = P_{F,t} C_{F,t} + (1-\xi) \cdot P_{H,t} K_{H,t+1} + \xi \cdot P_{F,t} K_{F,t+1}$$

- Euler equation: $E_t \beta (C_{i,t} / C_{i,t+1}) \alpha p_{i,t+1} Y_{i,t+1} / K_{i,t+1} = 1$

$$\Rightarrow \alpha \beta E_t \left\{ (P_{i,t} C_{i,t}) / (P_{i,t+1} C_{i,t+1}) \right\} (p_{i,t+1} Y_{i,t+1}) / (P_{i,t} K_{i,t+1}) = 1$$

- $\kappa_{i,t} \equiv P_{i,t} K_{i,t+1} / (P_{i,t} C_{i,t})$

$$\Rightarrow \alpha \beta E_t \left\{ 1 + \xi \kappa_{i,t+1} + (1-\xi) \kappa_{j,t+1} \right\} = \kappa_{i,t}$$

$\frac{1}{2} < \xi < 1$ spending home bias

$$\begin{bmatrix} E_t \kappa_{H,t+1} \\ E_t \kappa_{F,t+1} \end{bmatrix} = c + B \cdot \begin{bmatrix} \kappa_{H,t} \\ \kappa_{F,t} \end{bmatrix}, \text{ with } B = \frac{1}{\alpha\beta(2\xi-1)} \begin{bmatrix} \xi & -(1-\xi) \\ -(1-\xi) & \xi \end{bmatrix}.$$

eig(B) > 1

- Strictly positive process for Home and Foreign investment/consumption requires

$$\kappa_{H,t} = \kappa_{F,t} \geq 0$$

Bubble perfectly correlated across countries

- Investment bubble only in Home country:

⇒ growing Home trade deficit

⇒ would put Foreign investment on a downward trajectory.

⇒ Foreign capital could ultimately reach zero.

Logic of global bubbles also holds in BKK IRBC

(1) Bubbles, no TFP shocks.

(2) Just TFP shocks (no bubble)

(3) Bubbles & TFP shocks

CONCLUSIONS

- Stationary sunspot equilibria exist in standard *non-linear* DSGE models, even when the linearized versions of those models have unique solutions.
- In the sunspot equilibria considered here, the economy temporarily diverges from the no-sunspots trajectory, before abruptly reverting towards that trajectory.
- In multi-country model: bubble perfectly correlated across countries
